

ABSTRACT

Disclosed are methods of stimulating in a subject an immune response to an antigen to which the immune response is targeted. This method includes the step of administering to the subject a binding agent which binds a surface receptor of an antigen-presenting cell, in some instances without being blocked substantially by the natural ligand for the surface receptor, and an antigen to which the immune response is targeted, in a physiologically acceptable medium to the subject. Also disclosed are molecular complexes including the binding agent coupled to an antigen.
